Parallel Basic Blocks

Flattening Nested and Irregular Parallelism
Flattening Recipe
Irregular Multi-Dimensional Array Representation
Flattening Recipe (Redundant)
Rules For Flattening
Flattening by Function Lifting
Flattening Quicksort
Flattening Prime-Number (Sieve) Computation

- `zip :  [n]`α_1` `$\to$` [n]`α_2` `$\to$` [n](`α_1`,`α_2`)`
- `zip [a`$_1$`,...,a`$_n$`] [b`$_1$`,...,b`$_n$`]` $\equiv$
  `[(a`$_1$`,b`$_1$`),...,(a`$_n$`,b`$_n$`)],`

Zip, Unzip, iota, replicate

- `zip` : $[n]\alpha_1 \rightarrow [n]\alpha_2 \rightarrow [n](\alpha_1, \alpha_2)$
- `zip` $[a_1, \ldots, a_n]$ $[b_1, \ldots, b_n]$ $\equiv$
  $[(a_1, b_1), \ldots, (a_n, b_n)]$,

- `unzip` : $[n](\alpha_1, \alpha_2) \rightarrow ([n]\alpha_1, [n]\alpha_2)$
- `unzip`
  $[(a_1, b_1), \ldots, (a_n, b_n)] \equiv ([a_1, \ldots, a_n], [b_1, \ldots, b_n])$,

- In some sense `zip`/`unzip` are syntactic sugar

Zip, Unzip, iota, replicate

- zip : $[n]\alpha_1 \to [n]\alpha_2 \to [n](\alpha_1,\alpha_2)$
- zip $[a_1,\ldots,a_n]$ $[b_1,\ldots,b_n] \equiv$
  $[(a_1,b_1),\ldots,(a_n,b_n)],$

- unzip : $[n](\alpha_1,\alpha_2) \to ([n]\alpha_1,[n]\alpha_2)$
- unzip
  $[(a_1,b_1),\ldots,(a_n,b_n)] \equiv ([a_1,\ldots,a_n],[b_1,\ldots,b_n]),$
- In some sense zip/unzip are syntactic sugar

- replicate : (n: int) $\to \alpha \to [n]\alpha$
- replicate n a $\equiv$ [a, a,..., a],

Zip, Unzip, iota, replicate

- zip : $[n]\alpha_1 \rightarrow [n]\alpha_2 \rightarrow [n](\alpha_1,\alpha_2)$
- zip $[a_1,\ldots,a_n]$ $[b_1,\ldots,b_n] \equiv$
  $[(a_1,b_1),\ldots,(a_n,b_n)]$,

- unzip : $[n](\alpha_1,\alpha_2) \rightarrow ([n]\alpha_1,[n]\alpha_2)$
- unzip
  $[(a_1,b_1),\ldots,(a_n,b_n)] \equiv ([a_1,\ldots,a_n],[b_1,\ldots,b_n])$,

- In some sense zip/unzip are syntactic sugar

- replicate : (n: int) $\rightarrow \alpha \rightarrow [n]\alpha$
- replicate n a $\equiv$ [a, a,..., a],

- iota : (n: int) $\rightarrow$ [n]int
- iota n $\equiv$ [0, 1,..., n-1]

Note: in Haskell zip does not expect same-length arrays;
in Futhark it does!

Map, Reduce, and Scan Types and Semantics

- $[n]\alpha$ denotes the type of an array of n elements of type α.

- map : $(\alpha \to \beta) \to [n]\alpha \to [n]\beta$
  map f $[x_1,\ldots,x_n]$ = $[f\ x_1,\ldots,\ f\ x_n]$,
  i.e., $x_i\ :\ \alpha, \forall i$, and f $:\ \alpha \to \beta$.

- reduce : $(\alpha \to \alpha \to \alpha) \to \alpha \to [n]\alpha \to \alpha$
  reduce $\odot$ e $[x_1,x_2,\ldots,x_n]$ = $e \odot x_1 \odot x_2 \odot \ldots \odot x_n$,
  i.e., $e{:}\alpha,\quad x_i\ :\ \alpha, \forall i$, and $\odot\ :\ \alpha \to \alpha \to \alpha$.

- scan^{exc} : $(\alpha \to \alpha \to \alpha) \to \alpha \to [n]\alpha \to [n]\alpha$
  scan^{exc} $\odot$ e $[x_1,\ldots,x_n]$=$[e, e \odot x_1,\ldots,e \odot x_1 \odot \ldots x_{n-1}]$
  i.e., $e{:}\alpha,\ x_i\ :\ \alpha, \forall i$, and $\odot\ :\ \alpha \to \alpha \to \alpha$.

- scan^{inc} : $(\alpha \to \alpha \to \alpha) \to \alpha \to [n]\alpha \to [n]\alpha$
  scan^{inc} $\odot$ e $[x_1,\ldots,x_n]$ = $[e \odot x_1,\ldots,e \odot x_1 \odot \ldots x_n]$
  i.e., $e{:}\alpha,\ x_i\ :\ \alpha, \forall i$, and $\odot\ :\ \alpha \to \alpha \to \alpha$.

Map2, Filter

- $\text{map2}:(\alpha_1 \to \alpha_2 \to \beta) \ \to \ [\text{n}]\alpha_1 \ \to \ [\text{n}]\alpha_2 \ \to \ [\text{n}]\beta$

- $\text{map2} \ \odot \ [a_1,\ldots,a_n] \ [b_1,\ldots,b_n] \ \equiv \ [a_1 \odot b_1,\ldots,a_n \odot b_n]$

- $\text{map3} \ \ldots$

Map2, Filter

- map2 : $(\alpha_1 \to \alpha_2 \to \beta) \to [\mathtt{n}]\alpha_1 \to [\mathtt{n}]\alpha_2 \to [\mathtt{n}]\beta$

- map2 $\odot$ $[a_1,\ldots,a_n]$ $[b_1,\ldots,b_n]$ $\equiv$
  $[a_1 \odot b_1,\ldots,a_n \odot b_n]$

- map3 $\ldots$

- filter : $(\alpha \to \mathtt{Bool}) \to [\mathtt{n}]\alpha \to [\mathtt{m}]\alpha$ (m $\le$ n)

- filter p $[a_1,\ \ldots,\ a_n]$ = $[a_{k_1},\ldots,\ a_{k_m}]$ such that
  $k_1 < k_2 < \ldots < k_m$, and denoting $\overline{k} = k_1,\ldots,k_m$, we have
  (p a_j==true) $\forall j \in \overline{k}$, **and** (p a_j == false) $\forall j \notin \overline{k}$.

Note: in Haskell map2, map3 do not expect same-length arrays;
in Futhark they do!

Scatter: A Parallel Write Operator

Scatter updates in parallel a base array with a set of values at specified indices:

scatter : $^*[m]\alpha \rightarrow [n]int \rightarrow [n]\alpha \rightarrow {}^*[m]\alpha$

```
A (data vector)  =[b0,  b1,  b2,  b3]
I (index vector) =[2,   4,   1,   -1]
X (input array)  =[a0,  a1,  a2,  a3,  a4,  a5]
scatter X I A    =[a0,  b2,  b0,  a3,  b1,  a5]
```

Scatter: A Parallel Write Operator

Scatter updates in parallel a base array with a set of values at specified indices:

scatter : $^*[m]\alpha \to [n]\text{int} \to [n]\alpha \to {}^*[m]\alpha$

```
A (data vector)  =[b0,  b1,  b2,  b3]
I (index vector) =[2,   4,   1,  -1]
X (input array)  =[a0,  a1,  a2,  a3,  a4,  a5]
scatter X I A    =[a0,  b2,  b0,  a3,  b1,  a5]
```

scatter has $D(n) = \Theta(1)$ and $W(n) = \Theta(n)$,
i.e., requires n update operations (n is the size of I or A, not of X!).

1. Array X is consumed by `scatter`; following uses of X are illegal!
2. Similarly, X can alias neither I nor A!

In Futhark, `scatter` check and ignores the indices that are out of bounds (no update is performed on those). This is useful for padding the iteration space in order to obtain regular parallelism.

Partition2/Filter Implementation

partition2: $(\alpha \rightarrow Bool) \rightarrow [n]\alpha \rightarrow (i32,[n]\alpha)$
In result, the elements satisfying the predicate occur before the others. Can be implemented by means of map, scan, scatter.

```
let partition2 't [n]  (dummy: t)
      (cond: t -> bool) (X: [n]t) :
                          (i64, [n]t) =
 let cs = map cond X
 let tfs= map (\ f->if f then 1
                           else 0) cs
 let isT= scan (+) 0 tfs
 let i  = isT[n-1]

 let ffs = map (\f->if f then 0
                          else 1) cs
 let isF= map (+i) <| scan (+) 0 ffs
 let inds=map (\(c,iT,iF) ->
                   if c then iT-1
                        else iF-1
              ) (zip3 cs isT isF)
 let tmp = replicate n dummy
 in (i, scatter tmp inds X)
```

Assume X = [5,4,2,3,7,8], and cond is T(rue) for even nums.

Partition2/Filter Implementation

partition2: $(\alpha \rightarrow \text{Bool}) \rightarrow [n]\alpha \rightarrow (i32, [n]\alpha)$
In result, the elements satisfying the predicate occur before the others. Can be implemented by means of map, scan, scatter.

```
let partition2 't [n] (dummy: t)
        (cond: t -> bool) (X: [n]t) :
                        (i64, [n]t) =
 let cs = map cond X
 let tfs = map (\ f->if f then 1
                         else 0) cs
 let isT= scan (+) 0 tfs
 let i  = isT[n-1]

 let ffs= map (\f->if f then 0
                        else 1) cs
 let isF= map (+i) <| scan (+) 0 ffs
 let inds=map (\(c,iT,iF) ->
                if c then iT-1
                        else iF-1
              ) (zip3 cs isT isF)
 let tmp = replicate n dummy
 in (i, scatter tmp inds X)
```

```
Assume X = [5,4,2,3,7,8], and
cond is T(rue) for even nums.
n   = 6
cs  = [F, T, T, F, F, T]
tfs = [0, 1, 1, 0, 0, 1]

isT = [0, 1, 2, 2, 2, 3]
i   = 3

ffs = [1, 0, 0, 1, 1, 0]
isF = [4, 4, 4, 5, 6, 6]

inds= [3, 0, 1, 4, 5, 2]

flags  = [3, 0, 0, 3, 0, 0]
Result = [4, 2, 8, 5, 3, 7]
```

Segmented scan
Segmented Scan Is a Sort of Scan

Futhark Implementation:

```
def sgmscan 't [n] (op: t->t->t) (ne: t)
             (flg : [n]i64) (arr : [n]t) : [n]t =
  let flgs_vals =
    scan ( \ (f1, x1) (f2,x2) ->
            let f = f1 | f2 in
            if f2 != 0 then (f, x2)
            else (f, op x1 x2) )
         (0,ne) (zip flg arr)
  let (_, vals) = unzip flgs_vals
  in vals
```

```
sgmscan (+) 0 [1,0,0,1,0, 0, 0]          map (\ row -> scan (+) 0 row)
              [1,2,3,4,5, 6, 7]              [[1,2,3], [4,5, 6, 7]]
              = = = = = = = =                = = =    = = = =
              [1,3,6,4,9,15,22]              [[1,3,6], [4,9,15,22]]
```

Parallel Basic Blocks

Flattening Nested and Irregular Parallelism

Flattening Recipe
Irregular Multi-Dimensional Array Representation
Flattening Recipe (Redundant)
Rules For Flattening
Flattening by Function Lifting
Flattening Quicksort
Flattening Prime-Number (Sieve) Computation

How to Flatten? A Relatively Simple Case

```
let arr = [1, 2, 3, 4] in
map (\i -> map (+(i+1)) (iota i)) arr
-- Result: [[2],[3,4],[4,5,6],[5,6,7,8]]
```

Normalize the code:

```
let arr = [1, 2, 3, 4] in
map (\i -> map (+(i+1)) (iota i)) arr
-- Result: [[2],[3,4],[4,5,6],[5,6,7,8]]
```

Normalize the code:

```
map (\i -> let ip1 = i+1 in
           let iot = (iota i) in
           let ip1r= (replicate i ip1) in
           map2 (+) ip1r iot             ) arr
```

Distribute the map over every instruction in the body
(bottom-up if nest > 2), where $\mathcal{F}$ denotes the flattening transf,
and modify the inputs (results) accordingly.

How to Flatten? A Relatively Simple Case

```
let arr = [1, 2, 3, 4] in
map (\i -> map (+(i+1)) (iota i)) arr
-- Result: [[2],[3,4],[4,5,6],[5,6,7,8]]
```

Normalize the code:

```
map (\i -> let ip1 = i+1 in
           let iot = (iota i) in
           let ip1r= (replicate i ip1) in
           map2 (+) ip1r iot              ) arr
```

Distribute the map over every instruction in the body
(bottom-up if nest > 2), where $\mathcal{F}$ denotes the flattening transf,
and modify the inputs (results) accordingly.

```
𝓕(map (\i -> map (+(i+1)) (iota i)) [0..n-1]) ≡
1. let ip1s = map (\i -> i+1) arr in -- [2, 3, 4, 5]
2. let iots = 𝓕(map (\i -> (iota i)) arr) in
3. let ip1rs= 𝓕(map2 (\ i ip1 -> (replicate i ip1)) arr ip1s)
4. in  𝓕(map2 (\ ip1r iot -> map2 (+) ip1r iot) ip1rs iots)
```

How to Flatten? A Relatively Simple Case

According to rule (4) iota nested inside a map
(assuming $arr = [1,2,3,4]$):

```
2. let iots = F(map (\i -> iota i) arr)

≡

inds = scanexc (+) 0 arr -- [0,1,3,6]
size = (last inds) + (last arr) -- 6 + 4 = 10
flag = scatter (replicate size 0)
                inds arr
--              [1, 2, 0, 3, 0, 0, 4, 0, 0, 0]
tmp  = replicate size 1
iots = sgmScanexc (+) 0 flag tmp --[0, 0, 1, 0, 1, 2, 0, 1, 2, 3]
```

How to Flatten? A Relatively Simple Case

According to rule (3) replicate nested inside a map
(assuming `arr = [1,2,3,4]`):

```
3. let ip1rs= F(map2 (\ i ip1 -> replicate i ip1) arr ip1s)
≡
vals = scatter (replicate size 0) inds  ip1s -- [2,3,0,4,0,0,5,0,0,0]
ip1rs= sgmScan^inc (+) 0 flag vals           -- [2,3,3,4,4,4,5,5,5,5]
```

According to rule (2) map nested inside a map

```
F(map2 (\ ip1r iot -> map2 (+) ip1r iot) ip1rs iots)
≡
4. result = map (+) ip1rs iots
-- [2, 3, 3, 4, 4, 4, 5, 5, 5, 5]
-- [0, 0, 1, 0, 1, 2, 0, 1, 2, 3]
--  +  +  +  +  +  +  +  +  +  +
---------------------------------
-- [2, 3, 4, 4, 5, 6, 5, 6, 7, 8] values
-- [1, 2, 0, 3, 0, 0, 4, 0, 0, 0] flags
```

Parallel Basic Blocks

Flattening Nested and Irregular Parallelism

Shape-Based Representation

- Two dimensional arrays:

```
arr = [ [1,2,3] , [4] , [] , [5,6] ]
```
$\Rightarrow$
$S_{arr}^0 = [4]$
$S_{arr}^1 = [3, 1, 0, 2]$
$D_{arr} = [1, 2, 3, 4, 5, 6]$

Shape-Based Representation

- Two dimensional arrays:

  ```
  arr = [ [1,2,3], [4], [], [5,6] ]
  ```
  $\Rightarrow$
  $S_{arr}^0 = [4]$
  $S_{arr}^1 = [3, 1, 0, 2]$
  $D_{arr} = [1, 2, 3, 4, 5, 6]$

- Three dimensional arrays:

  ```
  arr = [ [], [ [1,2,3], [4], [], [5,6] ], [ [7], [], [8,9,10] ] ]
  ```
  $\Rightarrow$

Shape-Based Representation

- Two dimensional arrays:

```
arr = [ [1,2,3], [4], [], [5,6] ]
⇒
```
S_{arr}^0 = [4]
S_{arr}^1 = [3, 1, 0, 2]
D_{arr} = [1, 2, 3, 4, 5, 6]

- Three dimensional arrays:

```
arr = [ [], [ [1,2,3], [4], [], [5,6] ], [ [7], [], [8,9,10] ] ]
⇒
```
S_{arr}^0 = [3]
S_{arr}^1 = [0, 4, 3]
S_{arr}^2 = [3, 1, 0, 2, 1, 0, 3]
$flen_{arr}$ = 10
D_{arr} = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]

Assume a n-dimensional array; The following invariant holds:

length S_{arr}^i = reduce (+) 0 S_{arr}^{i-1} , $\forall 1 \leq i < n$
length D_{arr} = reduce (+) 0 S_{arr}^{n-1}

Flat Representation: Auxiliary Structures

```
arr = [ [], [ [1,2,3], [4], [], [5,6] ], [ [7], [], [8,9,10] ] ]
```
$\Rightarrow$
$S_{arr}^0 = [3]$
$S_{arr}^1 = [0, 4, 3]$
$S_{arr}^2 = [3, 1, 0, 2, 1, 0, 3]$
$D_{arr} = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]$

- Offset Indices (B): segment-start offset in the flat data:

  $B_{arr}^1 = [0, 0, 6]$
  $B_{arr}^2 = [0, 3, 4, 4, 6, 7, 7]$

- Flag Array (F): start of a segment indicated by a value !=0
  for example used for segmented scan operations:

  $F_{arr}^1 = [1, 0, 0, 0, 0, 0, 1, 0, 0, 0]$
  $F_{arr}^2 = [1, 0, 0, 1, 1, 0, 1, 1, 0, 0]$

- Segment and Inner indices (II):

  $II_{arr}^1 = [1, 1, 1, 1, 1, 1, 2, 2, 2, 2]$
  $II_{arr}^2 = [0, 0, 0, 1, 3, 3, 0, 2, 2, 2]$
  $II_{arr}^3 = [0, 1, 2, 0, 0, 1, 0, 0, 1, 2]$

Auxiliary Structures: Intuitive Motivation

Auxiliary structures are useful to optimize the replication of values.

Nested-Execution Example:

```
let xss = [ [1,2,3], [], [5,7] ]
let ys  = [ 4, 2, 1 ]
let rss = map2 (\ xs y -> map (+y) xs ) xss ys
⇒
rss = [ map (+4) [1,2,3], map (+2) [], map (+1) [5,7] ]
rss = [ [5,6,7], [], [6,8] ]
```

Traditional flattening would replicate the values of y:

```
let (S¹_yss,D_yss) = F(map2 (\xs y -> replicate (length xs) y) xss ys)
let D_rss = map2 (\ x y -> x + y) D_xss D_yss
⇒
D_xss = [1, 2, 3, 5, 7]
        +  +  +  +  +
D_yss = [4, 4, 4, 1, 1]
        =  =  =  =  =
D_rss = [5, 6, 7, 6, 8]
```

Auxiliary structures are useful to optimize the replication of values.

Nested-Execution Example:

```
let xss = [ [1,2,3], [], [5,7] ]
let ys  = [ 4, 2, 1 ]
let rss = map2 (\ xs y -> map (+y) xs ) xss ys
⇒
rss = [ map (+4) [1,2,3], map (+2) [], map (+1) [5,7] ]
rss = [ [5,6,7], [], [6,8] ]
```

Using the auxiliary structures we indirectly access other arrays:

```
let Drss = map2 (\ x sgmind -> x + ys[sgmind]) Dxss ||¹rss
⇒
```

$S^1_{rss} = [3, 0, 2]$
$||^1_{rss} = [0, 0, 0, 2, 2]$
$D_{xss} = [1, 2, 3, 5, 7]$
$D_{rss} = [1+4, 2+4, 3+4, 5+1, 7+1] = [5, 6, 7, 6, 8]$

But what have we gained? Creating $\texttt{II}^1_{rss}$ is as expensive as $\texttt{xss}$ (or better said the expanded $\texttt{yss}$ from the other slide) ...

Auxiliary Structures: Intuitive Motivation

Auxiliary structures are useful to optimize replication:

- they depend only on the shape of the result (created once)
- can indirectly access several lower-dimensional arrays, sharing parallel dimensions!

Nested-Execution Example:

```
let xss = [ [1,2,3], [], [5,7] ]
let ys  = [ 4, 2, 1 ]
let zs  = [ 1, 2, 3 ]
let rss = map3 (\ xs y z -> map (\x -> x*y + z ) xs ) xss ys zs
=>
rss = [ [5,9,13], [], [8,10] ]
```

Using the auxiliary structures we indirectly access other arrays:

```
let D_rss = map2 (\ y sgmind -> x*ys[sgmind] + zs[sgmind]) D_xss II^1_rss
=>
```

$$II^1_{rss} = [0, 0, 0, 2, 2]$$
$$D_{xss} = [1, 2, 3, 5, 7]$$
$$D_{rss} = [1*4+1, 2*4+1, 3*4+1, 5*1+3, 7*1+3] = [5, 9, 13, 8, 10]$$

We build II^1_{rss} once and reuse it twice; also improves locality!

Auxiliary Structures: Intuitive Motivation

Nested-Execution Example:

```
let xss = [ [1,3], [2] ]
let yss = [ [2], [4,5] ]
let rss = map2 (\xs ys -> map (\x -> map (+x) ys ) xs ) xss yss
⇒
rss = [ [[3],[5]], [[6,7]] ]
```

Using the auxiliary structures we indirectly access other arrays:

```
let D_rss = map3(\ s1 s2 s3 -> let ind_x = B¹_xss[s1] + s2
                               let ind_y = B¹_yss[s1] + s3
                               in  X[ind_x] + Y[ind_y]
               ) II¹_rss  II²_rss  II³_rss
```
$$\Rightarrow$$
$$B^1_{xss} = [0, 2]$$
$$B^1_{yss} = [0, 1]$$
$$II^1_{rss} = [0, 0, 1, 1]$$
$$II^2_{rss} = [0, 1, 0, 0]$$
$$II^3_{rss} = [0, 0, 0, 1]$$
$$D_{rss} = [\ D_{xss}[0+0]+D_{yss}[0+0],\ D_{xss}[0+1]+D_{yss}[0+0]$$
$$,\ D_{xss}[2+0]+D_{yss}[1+0],\ D_{xss}[2+0]+D_{yss}[1+1]\ ]$$
$$D_{rss} = [\ 1+2,\ 3+2,\ 2+4,\ 2+5] = [\ 3,\ 5,\ 6,\ 7]$$

Constructing the Offset Indices (B)

```
arr = [ [], [ [1,2,3], [4], [], [5,6] ], [ [7], [], [8,9,10] ] ]
⇒
```

$S_{arr}^0 = [3]$
$S_{arr}^1 = [0, 4, 3]$
$S_{arr}^2 = [3, 1, 0, 2, 1, 0, 3]$
$D_{arr} = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]$

Offset Indices (B): segment-start offset in the flat data:

$B_{arr}^1 = [0, 0, 6]$
$B_{arr}^2 = [0, 3, 4, 4, 6, 7, 7]$

How to construct Offset Indices (B)?

Constructing the Offset Indices (B)

```
arr = [ [], [ [1,2,3], [4], [], [5,6] ], [ [7], [], [8,9,10] ] ]
```
$\Rightarrow$

$S_{arr}^0 = [3]$
$S_{arr}^1 = [0, 4, 3]$
$S_{arr}^2 = [3, 1, 0, 2, 1, 0, 3]$
$D_{arr} = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]$

Offset Indices (B): segment-start offset in the flat data:

$B_{arr}^1 = [0, 0, 6]$
$B_{arr}^2 = [0, 3, 4, 4, 6, 7, 7]$

How to construct Offset Indices (B)?
By using exclusive scan on the shape!

$B_{arr}^2 = \text{scan}^{exc} \ (+) \ 0 \ S_{arr}^2$ *— [0, 3, 4, 4, 6, 7, 7]*

$B_{arr}^1 = \text{scan}^{exc} \ (+) \ 0 \ S_{arr}^1$ *— [0, 0, 4]*
$\quad\quad |> \text{map} \ (\backslash i \rightarrow B_{arr}^2[i])$ *— [0, 0, 6]*

Constructing the Flag Array

From now on, we discuss only TWO-dimensional irregular arrays!

```
def mkFlagArray 't [m]
            (aoa_shp: [m]i64)(zero: t)      —aoa_shp =[0,3,1,0,4,2,0]
            (aoa_val: [m]t)    : []t =      —aoa_val =[1,1,1,1,1,1]
  let shp_rot = map (\i->if i==0 then 0     —shp_rot =[0,0,3,1,0,4,2]
                           else aoa_shp[i-1]
                     ) (iota m)
  let shp_scn = scan (+) 0 shp_rot          —shp_scn =[0,0,3,4,4,8,10]
  let aoa_len = shp_scn[m-1]+aoa_shp[m-1]   —aoa_len= 10
  let shp_ind = map2 (\shp ind ->           —shp_ind=
                        if shp==0 then -1 —  [-1,0,3,-1,4,8,-1]
                        else ind          —scatter
                      ) aoa_shp shp_scn    —  [0,0,0,0,0,0,0,0,0,0]
  in scatter (replicate aoa_len zero)      —  [-1,0,3,-1,4,8,-1]
             shp_ind aoa_val               —  [1,1,1,1,1,1,1]
                                           —  F = [1,0,0,1,1,0,0,0,1,0]
```

Why do we need aoa_val?

Constructing the Flag Array

From now on, we discuss only TWO-dimensional irregular arrays!

```
def mkFlagArray 't [m]
            (aoa_shp: [m]i64)(zero: t)    —aoa_shp =[0,3,1,0,4,2,0]
            (aoa_val: [m]t)    : []t =    —aoa_val =[1,1,1,1,1,1]
  let shp_rot = map (\i—>if i==0 then 0   —shp_rot =[0,0,3,1,0,4,2]
                        else aoa_shp[i−1]
                    ) (iota m)
  let shp_scn = scan (+) 0 shp_rot        —shp_scn =[0,0,3,4,4,8,10]
  let aoa_len = shp_scn[m−1]+aoa_shp[m−1]—aoa_len= 10
  let shp_ind = map2 (\shp ind —>         —shp_ind=
                        if shp==0 then −1 —  [−1,0,3,−1,4,8,−1]
                        else ind          —scatter
                    ) aoa_shp shp_scn     — [0,0,0,0,0,0,0,0,0,0]
  in scatter (replicate aoa_len zero)     — [−1,0,3,−1,4,8,−1]
              shp_ind aoa_val             — [1,1,1,1,1,1,1]
                                    — F = [1,0,0,1,1,0,0,0,1,0]
```

Why do we need aoa_val?
Because there are many valid flag arrays, i.e., the start of the
segment can be denoted by any value different than zero!

Constructing the Segment and Inner Indices

From now on, we discuss only TWO-dimensional irregular arrays!

```
arr = [ [1,2,3], [4], [], [5,6], [7], [], [8,9,10] ]
⇒
```
$S_{arr}^0 = [7]$
$S_{arr}^1 = [3, 1, 0, 2, 1, 0, 3]$
$\text{flen}_{arr} = \text{reduce } (+) \ 0 \ S_{arr}^1 = 10$
$D_{arr} = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]$

Segment and Inner indices (II):

$II_{arr}^1 = [0, 0, 0, 1, 3, 3, 4, 6, 6, 6]$
$II_{arr}^2 = [0, 1, 2, 0, 0, 1, 0, 0, 1, 2]$

Constructing Segment and Inner indices (II):

$F_{arr} = \text{mkFlagArray } S_{arr}^1 \ 0 \ [1 \ldots \text{length } S_{arr}^1]$
        — [1, 0, 0, 2, 4, 0, 5, 7, 0, 0]

$II_{arr}^1 = ???$
$II_{arr}^2 = ???$

Constructing the Segment and Inner Indices

I need to get this:

II^1_{arr} = [0, 0, 0, 1, 3, 3, 4, 6, 6, 6]

from this:

F_{arr} = mkFlagArray S^1_{arr} 0 [1 ... length S^1_{arr}]
      — [1, 0, 0, 2, 4, 0, 5, 7, 0, 0]

How ?

I need to get this:

II^2_{arr} = [0, 1, 2, 0, 0, 1, 0, 0, 1, 2]

from this:

F_{arr} = mkFlagArray S^1_{arr} 0 [1 ... length S^1_{arr}]
    — [1, 0, 0, 2, 4, 0, 5, 7, 0, 0]

How?

Constructing the Segment and Inner Indices

From now on, we discuss only TWO-dimensional irregular arrays!

```
arr = [ [1,2,3], [4], [], [5,6], [7], [], [8,9,10] ]
⇒
S⁰ₐᵣᵣ = [7]
S¹ₐᵣᵣ = [3, 1, 0, 2, 1, 0, 3]
flenₐᵣᵣ = reduce (+) 0 S¹ₐᵣᵣ = 10
Dₐᵣᵣ = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

Segment and Inner indices (II):

```
II¹ₐᵣᵣ = [0, 0, 0, 1, 3, 3, 4, 6, 6, 6]
II²ₐᵣᵣ = [0, 1, 2, 0, 0, 1, 0, 0, 1, 2]
```

Constructing Segment and Inner indices (II):

```
Fₐᵣᵣ = mkFlagArray S¹ₐᵣᵣ 0 [1...length S¹ₐᵣᵣ]
       — [1, 0, 0, 2, 4, 0, 5, 7, 0, 0]
II¹ₐᵣᵣ = sgmscan (+) 0 Fₐᵣᵣ Fₐᵣᵣ |> map (−1)
II²ₐᵣᵣ = sgmscan (+) 0 Fₐᵣᵣ (replicate flen 1) |> map (−1)
```

Parallel Basic Blocks

Flattening Nested and Irregular Parallelism

```
let arr = [1, 2, 3, 4] in
map (\i -> map (+(i+1)) (iota i)) arr
-- Result: [[2],[3,4],[4,5,6],[5,6,7,8]]
```

```
let arr = [1, 2, 3, 4] in
map (\i -> map (+(i+1)) (iota i)) arr
-- Result: [[2],[3,4],[4,5,6],[5,6,7,8]]
```

Normalize the code:

```
map (\i -> let ip1 = i+1 in
           let iot = (iota i) in
           let ip1r= (replicate i ip1) in
           map2 (+) ip1r iot            ) arr
```

Distribute the map over every instruction in the body
(bottom-up if nest > 2), where $\mathcal{F}$ denotes the flattening transf,
and modify the inputs (results) accordingly.

```
let arr = [1, 2, 3, 4] in
map (\i -> map (+(i+1)) (iota i)) arr
-- Result: [[2],[3,4],[4,5,6],[5,6,7,8]]
```

Normalize the code:

```
map (\i -> let ip1 = i+1 in
           let iot = (iota i) in
           let ip1r= (replicate i ip1) in
           map2 (+) ip1r iot            ) arr
```

Distribute the map over every instruction in the body
(bottom-up if nest > 2), where $\mathcal{F}$ denotes the flattening transf,
and modify the inputs (results) accordingly.

```
𝓕(map (\i -> map (+(i+1)) (iota i)) [0..n-1]) ≡
1. let ip1s = map (\i -> i+1) arr in -- [2, 3, 4, 5]
2. let iots = 𝓕(map (\i -> (iota i)) arr) in
3. let ip1rs= 𝓕(map2 (\ i ip1 -> (replicate i ip1)) arr ip1s)
4. in  𝓕(map2 (\ ip1r iot -> map2 (+) ip1r iot) ip1rs iots)
```

According to rule (4) iota nested inside a map
(assuming `arr = [1,2,3,4]`):

```
2. let iots = ℱ(map (\i -> iota i) arr)

≡

inds = scanᵉˣᶜ (+) 0 arr -- [0,1,3,6]
size = (last inds) + (last arr) -- 6 + 4 = 10
flag = scatter (replicate size 0)
                inds arr
--              [1, 2, 0, 3, 0, 0, 4, 0, 0, 0]
tmp  = replicate size 1
iots = sgmScanᵉˣᶜ (+) 0 flag tmp --[0, 0, 1, 0, 1, 2, 0, 1, 2, 3]
```

How to Flatten? A Relatively Simple Case

According to rule (3) replicate nested inside a map
(assuming `arr = [1,2,3,4]`):

```
3. let ip1rs= 𝓕(map2 (\ i ip1 -> replicate i ip1) arr ip1s)
≡
vals = scatter (replicate size 0) inds  ip1s -- [2,3,0,4,0,0,5,0,0,0]
ip1rs= sgmScan^{inc} (+) 0 flag vals         -- [2,3,3,4,4,4,5,5,5,5]
```

According to rule (2) map nested inside a map

```
𝓕(map2 (\ ip1r iot -> map2 (+) ip1r iot) ip1rs iots)
≡
4. result = map (+) ip1rs iots
-- [2, 3, 3, 4, 4, 4, 5, 5, 5, 5]
-- [0, 0, 1, 0, 1, 2, 0, 1, 2, 3]
--  +  +  +  +  +  +  +  +  +  +
--------------------------------
-- [2, 3, 4, 4, 5, 6, 5, 6, 7, 8] values
-- [1, 2, 0, 3, 0, 0, 4, 0, 0, 0] flags
```

Parallel Basic Blocks

Flattening Nested and Irregular Parallelism

(1) Scan inside a nested map:

```
res = map (\row->scan^{inc} (+) 0 row) [[1,3], [2,4,6]]
≡
res = [ scan^{inc} (+) 0 [1,3],    scan^{inc} (+) 0 [2,4,6] ]
≡
res = [ [ 1, 4],                [2, 6, 12] ]
```

Nested *vs* Flattened Parallelism: Scan inside a Map

(1) Scan inside a nested map:

```
res = map (\row->scan^inc (+) 0 row) [[1,3], [2,4,6]]
≡
res = [ scan^inc (+) 0 [1,3],    scan^inc (+) 0 [2,4,6] ]
≡
res = [ [ 1, 4],                 [2, 6, 12] ]
```

becomes a segmented scan, which requires a flag array as arg:

```
sgmScan^inc (+) 0 [1, 0, 1, 0, 0] [1, 3, 2, 4, 6] ≡ [ 1, 4, 2, 6, 12 ]
```

Flattening a scan directly nested inside a map:

- the flat-data array is obtained by a segmented scan;
- the shape of the result array is the same as the input array.

$\mathcal{F}($`res = map (\row -> scan (⊙) 0⊙ row) arr`$) \Rightarrow$

$S^1_{res} = S^1_{arr}$

$D_{res} =$ sgmScan $(⊙)\ 0_⊙\ F_{arr}\ D_{arr}$

(2) Map nested inside a map:

```
res = map (\row->map f row) [[1,3], [2,4,6]]
≡
res = [ map f [1, 3],      map f [2, 4, 6] ]
≡
res = [ [f(1),f(3)], [f(2),f(4),f(6)] ]
```

(2) Map nested inside a map:

```
res = map (\row->map f row) [[1,3], [2,4,6]]
≡
res = [ map f [1, 3],      map f [2, 4, 6] ]
≡
res = [ [f(1),f(3)], [f(2),f(4),f(6)] ]
```

Flattening a map directly nested inside a map:

- the flat-data array is obtained by a map on the flat input;
- the shape of the result array is the same as the input array.

$\mathcal{F}($`res = map (\row -> map f row) arr`$) \Rightarrow$

$S_{res}^1 = S_{arr}^1$

$D_{res} = $ map f D_{arr}

(3) Replicate nested inside a map:

```
res = map2 (\ n m -> replicate n m) [1,0,3,2] [7,3,8,9] ≡
res = [ replicate 1 7, replicate 0 3, replicate 3 8, replicate 2 9 ] ≡
res = [ [7], [], [8,8,8], [9,9] ]
```

(3) Replicate nested inside a map:

```
res = map2 (\ n m -> replicate n m) [1,0,3,2] [7,3,8,9] ≡
res = [ replicate 1 7, replicate 0 3, replicate 3 8, replicate 2 9 ] ≡
res = [ [7], [], [8,8,8], [9,9] ]

res = map2(\n m-> replicate n m) ns ms
```
becomes a scan-scatter composition:

(3) Replicate nested inside a map:

```
res = map2 (\ n m -> replicate n m) [1,0,3,2] [7,3,8,9] ≡
res = [ replicate 1 7, replicate 0 3, replicate 3 8, replicate 2 9 ] ≡
res = [ [7], [], [8,8,8], [9,9] ]
```

```
res = map2(\n m-> replicate n m) ns ms
```
becomes a scan-scatter composition:

1. the shape of the result array is `ns`
2-3. builds the indices at which segment start (-1 for null shape)
4. get the size of the flat array (summing `ns`)
5-6. write the `ms` and `ns` values at the start of their segments
7. propagate the `ms` values throughout their segments.
   - Implementation shortcomings:

Nested *vs* Flattened Parallelism: Replicate in a Map

(3) Replicate nested inside a map:

```
res = map2 (\ n m -> replicate n m) [1,0,3,2] [7,3,8,9] ≡
res = [ replicate 1 7, replicate 0 3, replicate 3 8, replicate 2 9 ] ≡
res = [ [7], [], [8,8,8], [9,9] ]

res = map2(\n m-> replicate n m) ns ms
```
becomes a scan-scatter composition:

1. the shape of the result array is ns
2-3. builds the indices at which segment start (-1 for null shape)
4. get the size of the flat array (summing ns)
5-6. write the ms and ns values at the start of their segments
7. propagate the ms values throughout their segments.
   - Implementation shortcomings: sgmScan^{inc} (+)?

$\mathcal{F}$(res = map2 (\n m -> replicate n m) ns ms) ⇒   — ms = [7,3,8,9]

1. S_{res}^1 = ns   — ns = [1,0,3,2]
2. inds = scan^{exc} (+) 0 ns   — [0,1,1,4]
3. |> map2 (\n i->**if** n>0 **then** i **else** −1) ns   — inds = [0,−1,1,4]
4. size = (last inds) + (last ns)   — 4 + 2 = 6
5. vls = scatter (replicate size 0) inds ms   — [7, 8, 0, 0, 9, 0]
6. F$_{arr}$ = scatter (replicate size 0) inds ns   — [1, 3, 0, 0, 2, 0]
6. D$_{res}$ = sgmScan^{inc} (+) 0 F$_{res}$ vls   — [7, 8, 8, 8, 9, 9]

(4) Iota nested inside a map ((iota n)≡[0,...,n-1]):

```
res = map (\i -> iota i) [1,3,2] ≡
res = [ iota 1, iota 3, iota 2 ] ≡ [ [0], [0,1,2], [0,1] ]
```

Nested *vs* Flattened Parallelism: Iota in a Map

(4) Iota nested inside a map ($(\texttt{iota n})\equiv[0,\ldots,\texttt{n-1}]$):

```
res = map (\i -> iota i) [1,3,2] ≡
res = [ iota 1, iota 3, iota 2 ] ≡ [ [0], [0,1,2], [0,1] ]
```

boils down to a segmented scan applied to an array of ones:

1. by definition of iota, $\texttt{ns}$ contains the size of each subarray, hence the shape of the result is $\texttt{ns}$;
2. the flag-array of the result, F_{res}, is constructed from $\texttt{ns}$;
3. the result is obtained by an exclusive segmented scan operation applied to an array of ones.

$\mathcal{F}(\texttt{res = map (\n -> iota n) ns}) \Rightarrow$

1. $S^1 res$ = ns   — $ns = [1, 3, 2]$
2. F_{res} = mkFlagArray ns 0 ns   — $F_{res} = [1, 1, 0, 0, 1, 0]$
3. D_{res} = sgmScan^{exc} (+) 0 F_{res} (replicate flen$_{res}$ 1) — $[0, 0, 1, 2, 0, 1]$

Note that iota n $\equiv$ scan^{exc} (+) 0 (replicate n 1).

(5) Reduce Inside a Map or Segmented Reduce:

```
let arr = [[1, 3, 4], [6, 7]] in
let res = map (\x -> reduce (+) 0 x) arr
-- should result in [8, 13]
```

(5) Reduce Inside a Map or Segmented Reduce:

```
let arr = [[1, 3, 4], [6, 7]] in
let res = map (\x -> reduce (+) 0 x) arr
-- should result in [8, 13]
```

translates to a scan-pack composition:

1. the length of `res` equals the number of subarrays of `arr`;
2. the shape of `arr` is scanned: the result records the position of the last element in a segment plus one;
3. segmented scan is applied on the input array: the last elem in a segment holds the reduced value of the segment;
4. segment's last element is extracted by a map operation.

$\mathcal{F}($ res = map $(\backslash$ row $\rightarrow$ reduce $\odot$ $0_\odot$ row) arr $) \Rightarrow$

— $S_{arr}^0 = [2]$, $S_{arr}^1 = [3,2]$, $F_{arr} = [1,0,0,1,0]$, $D_{arr} = [1,3,4,6,7]$

1. $S_{res}^0 = S_{arr}^0$ — $S_{res}^0 = [2]$
2. indsp1 = scan (+) 0 S_{arr}^1 — indsp1 = [3, 5]
3. tmp = sgmScan $(\odot)$ $0_\odot$ F_{arr} D_{arr} — tmp = [1, 4, 8, 6, 13]
4. D_{res} = map2($\backslash$ s ip1 $\rightarrow$ **if** s$\leq$0 **then** $0_\odot$
                              else tmp[ip1-1]) S_{arr}^1 indsp1 — $D_{res} = [8, 13]$

(6) The inner construct uses a scalar variant to the outer map:

```
let res = map2 (\x ys -> map (+x) ys) [1,3] [[4,5,6], [9,7]] ≡
let res = [map (+1) [4,5,6], map (+3) [9,7]]
let res = [ [5,6,7], [12,10] ]
```

(6) The inner construct uses a scalar variant to the outer map:

```
let res = map2 (\x ys -> map (+x) ys) [1,3] [[4,5,6], [9,7]] ≡
let res = [map (+1) [4,5,6], map (+3) [9,7]]
let res = [ [5,6,7], [12,10] ]
```

Traditionally, this is handled by expanding (replicating) each x across the whole segment

```
let Dxss = [1, 1, 1, 3, 3]
let res = map2 (+) [1, 1, 1, 3,  3 ]
                   [4, 5, 6, 9,  7 ]
                    =  =  =  =   =
                   [5, 6, 7, 12, 10]
```

Instead, we use $\mathtt{II}_{arr}^1$ to indirectly access in the xs array:

$\mathcal{F}(\text{res} = \text{map2 } (\backslash x \ ys \rightarrow \text{map (f } x)\ ys)\ xs\ yss) \Rightarrow$
— $xs = [1,3],\ S_{yss}^1 = [3,2],\ F_{yss} = [1,0,0,1,0],\ D_{yss} = [4,5,6,9,7]$
1. $S_{res}^1 = S_{yss}^1$
2. $D_{res} = \text{map2 } (\backslash y \ \text{sgmind} \rightarrow f \ xs[\text{sgmind}]\ y\ )\ \ D_{yss}\ II_{yss}^1$
— $II_{yss}^1 = [0,0,0,1,1],\ D_{res} = [5,6,7,12,10]$

(7) Indexing Operations Variant to the Outer Map:

```
let res = map2 (\i xs -> xs[i]) [2,0] [[4,5,6], [9,7]] ≡
let res = [ 6, 9 ]
```

(7) Indexing Operations Variant to the Outer Map:

```
let res = map2 (\i xs -> xs[i]) [2,0] [[4,5,6], [9,7]] ≡
let res = [ 6, 9 ]
```

To corresponding flat index in D_{yss} is obtained by summing up

- the start offset of every segment, which we get from B_{yss}^1, and
- the index inside the segment, which we get from `is`

$\mathcal{F}(\text{res} = \text{map2} \ (\backslash i \ xs \rightarrow xs[i]) \ is \ xss) \Rightarrow$

— $is = [2,0], \ S_{xss}^1 = [3,2], \ B_{xss}^1 = [0,3], \ D_{xss} = [4,5,6,9,7]$

1. $S_{res}^0 = S_{is}^0$ — $= S_{is}^0 = [2]$

2. $D_{res} = \text{map2} \ (\backslash \ \text{off} \ i \rightarrow D_{xss}[\text{off} + i]) \ B_{xss}^1 \ is$ — $D_{res} = [6, \ 9]$

(8) If-Then-Else with inner parallelism nested inside a map:

```
bs  = [F,T,F,T]
xss = [[1,2,3],[4,5,6,7],[8,9],[10]]
res = map(\b xs -> if b  then map (+1) xs  else map (*2) xs) bs xss
res = [ map(*2)[1,2,3], map(+1)[4,5,6,7], map(*2)[8,9], map(+1)[10] ]
res = [ [2,4,6], [5,6,7,8], [16,18], [11] ]
```

(8) If-Then-Else with inner parallelism nested inside a map:

```
bs  = [F,T,F,T]
xss = [[1,2,3],[4,5,6,7],[8,9],[10]]
res = map(\b xs -> if b  then map (+1) xs  else map (*2) xs) bs xss
res = [ map(*2)[1,2,3], map(+1)[4,5,6,7], map(*2)[8,9], map(+1)[10] ]
res = [ [2,4,6], [5,6,7,8], [16,18], [11] ]
```

translates to a scatter-map-gather composition. Intuition:

1. compute `iinds`, the permutation of segments w.r.t. `bs`;

2-3. partition the `xss` array based on `bs`;

4-5. **flatten outer map and/on top of the parallel code of the** `then` **and** `else` **branches;**

6. inverse permute the resulted segments according to `iinds`.

```
1. iinds = partition2 (λi -> bs[i]) (iota (length b)) -- [1,3,0,2]
2. xss_then = gatherThen iinds xss -- ([4,1], [4,5,6,7, 10])
3. xss_else = gatherElse iinds xss -- ([3,2], [1,2,3,  8,9])
4. res_then = map (+1) xss_then -- ([4,1], [5,6,7,8, 11]) Flattened rec!
5. res_else = map (*2) xss_else -- ([3,2], [2,4,6,16,18])  Flattened rec!
6. res = inversePermute iinds (res_then++res_else)
-- ([3,4,2,1], [2,4,6, 5,6,7,8, 16,18, 11])
```

(8) If-Then-Else with inner parallelism nested inside a map:

bs = [F,T,F,T], xss = [[1,2,3],[4,5,6,7],[8,9],[10]], S^1_{xss}=[3,4,2,1], f=map (+1), g=map (*2)

$\mathcal{F}$(res = map2 (\b xs -> if b **then** f xs **else** g xs) bs xss) $\Rightarrow$

(spl , iinds) = partition2 bs (iota (length bs)) — *(2 , [1,3,0,2])*

($S^1_{xss_{then}}$, $S^1_{xss_{else}}$) = split spl (map (\ ii -> S^1_{xss}[ii]) iinds)—*([4 ,1] ,[3 ,2])*

$mask_{xss}$ = map (\sgmind -> bs[sgmind]) II^1_{xss} — *[F,F,F,T,T,T,T,F,F,T]*

(brk , D^p_{xss}) = partition2 $mask_{xss}$ D_{xss}

($D_{xss_{then}}$, $D_{xss_{else}}$) = split brk D^p_{xss} — *([4 ,5 ,6 ,7 ,10] ,[1 ,2 ,3 ,8 ,9])*

($S^1_{res_{then}}$, $D_{res_{then}}$) = $\mathcal{F}$(map f) ($S^1_{xss_{then}}$, $D_{xss_{then}}$) — *([4 ,1] , [5 ,6 ,7 ,8 ,11])*

($S^1_{res_{else}}$, $D_{res_{else}}$) = $\mathcal{F}$(map g) ($S^1_{xss_{else}}$, $D_{xss_{else}}$) — *([3 ,2] , [2 ,4 ,6 ,16 ,18])*

S^{1P}_{res} = $S^1_{res_{then}}$++$S^1_{res_{else}}$ — *[4 ,1 ,3 ,2]*

S^1_{res} = scatter (replicate (length bs) 0) iinds S^{1P}_{res} — *[3,4,2,1]*

B^1_{res} = $scan^{exc}$ (+) 0 S^1_{res} — *[0,3,7,9]*

F^P_{res} = mkFlagArray S^{1P}_{res} 0 (map (+1) iinds) — *[2,0,0,0,4,1,0,0,3,0]*

II^{1P}_{res} = sgmscan (+) 0 F^P_{res} F^P_{res} |> map (−1) — *[1,1,1,1,3,0,0,0,2,2]*

II^{2P}_{res} = $II^2_{res_{then}}$++$II^2_{res_{else}}$ — *[0,1,2,3,0, 0,1,2,0,1]*

$sinds_{res}$ = map2 (\sgm iin -> B^1_{res}[sgm] + iin) II^{1P}_{res} II^{2P}_{res}

— *[3+0,3+1,3+2,3+3, 9+0, 0+0,0+1,0+2, 7+0,7+1]=[3,4,5,6,9,0,1,2,7,8]*

D_{res} = scatter (replicate $flen_{res}$ 0) $sinds_{res}$ ($D_{res_{then}}$++$D_{res_{else}}$)

— *[2,4,6, 5,6,7,8, 16,18, 11]*

(S^1_{res} , D_{res})

(9) Flattening a Do Loop Nested Inside a Map:

- compute the maximal loop count n_{max}
- interchange the loop and the map:
  - ▶ loop count becomes n_{max}
  - ▶ the loop body is wrapped inside a `if i<n` condition, and
  - ▶ the new loop body is flattened!

$\mathcal{F}(\text{res} = \text{map2} \ (\backslash n \ xs \ -> \ \textbf{loop} \ (xs) \ \textbf{for} \ i < n \ \textbf{do} \ f \ xs) \ ns \ xss) \Rightarrow$

1. $n_{max} = \text{reduce max } 0 i 32 \ ns$
2. $g \ i \ m \ arr = \textbf{if} \ i < m \ \textbf{then} \ f \ arr \ \textbf{else} \ arr$
3. $\textbf{loop} \, (S^1_{xss} \, , \, D_{xss}) \ \textbf{for} \ i < n_{max} \ \textbf{do}$
4. $\quad \mathcal{F}(\text{map2} \ (g \ i)) \ ns \ (S^1_{xss} \, , \, D_{xss})$
5. $\quad \text{——} \ (g \ i)^L \ ns \ (S^1_{xss}, D_{xss})$

But this treatment does not necessarily preserve the work asymptotic … what to do?

Parallel Basic Blocks

Flattening Nested and Irregular Parallelism

Flattening by Function Lifting: Basic Idea

Assume a simple function f:

```
let f (x: i32) : i32 = x + 1
```

f lifted, denoted f^L semantically corresponds to map f, where the arguments have been expanded to an extra array dimension, and the inner operators/functions have also been lifted:

```
let +L [n] (as: [n]i32) (bs: [n]i32) : [n]i32 =
    map2 (+) as bs

let fL [n] (xs: [n]i32) : [n]i32 =
    xs +L (replicate n 1)
```

Flattening by Function Lifting: Basic Idea

Assume a simple function f:

```
let f (x: i32) : i32 = x + 1
```

f lifted, denoted f^L semantically corresponds to map f, where the arguments have been expanded to an extra array dimension, and the inner operators/functions have also been lifted:

```
let +L [n] (as: [n]i32) (bs: [n]i32) : [n]i32 =
    map2 (+) as bs
```

```
let fL [n] (xs: [n]i32) : [n]i32 =
    xs +L (replicate n 1)
```

- Locals such as x $\Rightarrow$ left alone
- Global such as + $\Rightarrow$ lifted ($+^L$)
- Constants such as k $\Rightarrow$ replicate (length xs) k
  - ▶ good for vectorization, bad for locality, asymptotics
  - ▶ for GPU better to indirectly index into a smaller array, rather than replicate.

```
let f (xs: []i32) : []i32 = map g xs  -- = g^L xs
let f^L (xss: [][]i32) : [][]i32 = (g^L)^L  -- ???
```

How do we stop lifting? g and g^L are enough: no need for $(g^L)^L$!

Flattening by Function Lifting: Key Insight!

```
let f (xs: []i32) : []i32 = map g xs -- = gᴸ xs
let fᴸ (xss: [][]i32) : [][]i32 = (gᴸ)ᴸ -- ???
```

How do we stop lifting? g and g^L are enough: no need for $(g^L)^L$!

```
let f (xs: []i32) : []i32 = map g xs -- = gᴸ xs
-- in nested parallel form
let fᴸ (xss: [][]i32) : [][]i32 =
    segment xss (gᴸ (concat xss))
-- in flatten form
let fᴸ (S¹ₓₛₛ: []i32, Dₓₛₛ: []i32) : ([]i32, []i32) =
    (S¹ₓₛₛ, gᴸ Dₓₛₛ)
```

In Haskell Notation:

```
concat  :: [[a]]  -> [a]
segment :: [[a]]  -> [b]      ->   [[b]]
           shape    flat data    nested data
```

Parallel Basic Blocks

Flattening Nested and Irregular Parallelism

Recounting Quicksort

Recount the classic nested-parallel definition:

```
let quicksort [n] (arr : [n]f32) : [n]f32 =
  if n < 2 then arr else
  let i = getRand (0, (length arr) − 1)
  let a = arr[i]
  let s1 = filter (< a) arr
  let s2 = filter (== a) arr
  let s3 = filter (> a) arr
  in (quicksort s1) ++ s2 ++ (quicksort s3)
  -- can be re-written as:
  -- rs = map nestedQuicksort [s1, s3]
  -- in (rs[0]) ++ s2 ++ (rs[1])
```

Note: Futhark does not support recursive calls, hence not valid
code!

Nested-Parallel Quicksort Simplified

For simplicity we will rewrite it in terms of `partition2`:

```
let isSorted [n] (as: [n]f32) : bool =
    map (\ i -> if i==0 then true else as[i-1] < as[i]) (iota n)
    |> reduce (&&) true

let quicksort [n] (arr: [n]f32) : [n]f32 =
  if isSorted arr then arr else
  let i = getRand (0, (length arr) - 1)
  let a = arr[i]
  let bs = map (< a) arr
  let (q, arr') = partition2 bs 0.0f32 arr
  let (arr_<, arr_>) = split q arr'
  in  concat <| map quicksort [arr_<, arr_>]
```

Note: Futhark does not support recursive calls, irregular map
operation, or concat!

Partition2

Reorders the elements of an array such that those that correspond to a true mask come before those corresponding to false.

```
let partition2 [n] 't (conds: [n]bool) (dummy: t) (arr: [n]t)
        : (i32, [n]t) =
  let tflgs = map (\ c -> if c then 1 else 0) conds
  let fflgs = map (\ b -> 1 - b) tflgs

  let indsT = scan (+) 0 tflgs
  let tmp   = scan (+) 0 fflgs
  let lst   = if n > 0 then indsT[n-1] else -1
  let indsF = map (+ lst) tmp

  let inds  = map3 (\ c indT indF -> if c then indT-1 else indF-1)
                   conds indsT indsF

  let fltarr= scatter (replicate n dummy) inds arr
  in (lst, fltarr)
```

For example:

```
conds = [F,T,F,T,F,F,T]
xss =   [1,2,3,4,5,6,7]
partition2 conds 0 xss => (3, [2,4,7,1,3,5,6])
```

Lifting Quicksort

Key Idea: write a function with the semantics of
`map nestedQuicksort`, i.e., it operates on array of arrays.

```
let isSorted [n] (as: [n]f32) : bool =
    map (\ i -> if i==0 then true else as[i-1] < as[i]) (iota n)
    |> reduce (&&) true

let quicksort$^L$ (xss: [][]f32) : [][]f32 =
  map (\ xs ->
        if isSorted xs then xs else  -- oh, boy, not if-then-else!
        let i = getRand (0, (length xs) - 1)
        let a = xs[i]
        let bs = map (< a) xs
        let (q, xs$^p$) = partition2 bs 0.0f32 xs
        let (xs$_<$, xs$_\geq$) = split q xs$^p$
        in   concat <| map quicksort [xs$_<$, xs$_\geq$]
  ) xss
```

Important observations:
- map quicksort $\equiv$ quicksort^L
- map(map quicksort)$\equiv$quicksort$^{L^L}$$\equiv$segment o quicksort^{L}o concat
- the flat data of [xs$_<$, xs$_\geq$] $\equiv$ xs^p, the result of `partition2`

Lifting Quicksort

Let us treat the last three lines from the previous implem:.

```
let quicksort^L (S^1_{xss}:[]i32, D_{xss}:[]f32): ([]i32,[]f32) = —(xss: [][]f32)
  if isSorted D_{xss} then (S^1_{xss}:[]i32, D_{xss}:[]f32) else — big cheat!
  let (S^1_{bss}, D_{bss}) = F (
      map (\xs ->
              let i = getRand (0, (length xs) − 1)
              let a = xs[i]
              let bs = map (< a) xs
              in  bs
          ) xss
    )
  let (ps, (S^1_{xss^p},D_{xss^p})) = partition2^L D_{bss} 0.0f32 (S^1_{xss}, D_{xss})
  — Invariant: S^1_{xss^p} == S^1_{bss} == S^1_{xss}
  let S^1_{[xss_<,xss_≥]} = filter (!=0) <| flatten <|
          map2 (λ p s -> if s==0 then [0,0] else [p,s−p]) ps S^1_{xss}
  in  quicksort^L (S^1_{[xss_<,xss_≥]}, D_{xss^p})
```

- $S^1_{[xss_{<a},xss_{≥a}]}$ is the shape of $[xs_<, \; xs_≥]$
- $(concat <| quicksort^L)^L \; xsss \equiv concat <| segment \; xsss <|$
  $quicksort^L \; (concat \; xsss) \equiv quicksort^L \; (concat \; xsss)$
- The function looks tail recursive now: let's replace it with a loop!

Lifting Quicksort: Final Implementation

```
let quicksort^L [m][n] (S^1_xss:[m]i32 , D_xss:[n]f32): [n]f32 =
  let (stop , count) = (isSorted D_xss , 0i32)
  let (_ , res , _ , _) =
    loop(S^1_xss , D_xss , stop , count) while (!stop) do
        -- compute helper-representation structures
        let B^1_xss = scan^exc (+) 0 S^1_xss
        let F^1_xss = mkFlagArray S^1_xss 0i32 <| map (+1) <| iota m
        let II^1_xss = sgmscan (+) 0 F^1_xss <|
                map (\ f -> if f==0 then 0 else f-1) F^1_xss
        -- flattening quicksort:
        let rL = map (\u -> randomInd (0 ,u-1) count) S^1_xss
        let aL = map3(\r l i-> if l <= 0 then 0.0 else D_xss[B^1_xss[i]+r]
                     ) rL S^1_xss (iota m)
        let D_bss= map2 (\x sgmind -> aL[sgmind] > x ) D_xss II^1_xss
        let (ps , (S^1_xss^p ,D^per_xss)) = partition2^L D_bss 0.0f32 (S^1_xss , D_xss)
        let S^1_[xss_<,xss_>] = filter (!=0) <| flatten <|
                map2 (\ p s -> if s==0 then [0 ,0] else [p ,s-p]) ps S^1_xss
        in (S^1_[xss_<,xss_>] , D^per_xss , isSorted D^per_xss , count+1)
  in  res
```

PFP Weekly 2 Exercise: Implement `partition2^L`

Parallel Basic Blocks

Flattening Nested and Irregular Parallelism

The important bit with nested parallelism:

```
sqrt_primes = primesOpt (sqrt (fromIntegral n))
nested = map (\p -> let m = (n `div` p)
                    in  map (\j -> j*p) [2..m]
             ) sqrt_primes
not_primes  = reduce (++) [] nested
```

How Does One Flattens Prime Numbers?

The important bit with nested parallelism:
```
sqrt_primes = primesOpt (sqrt (fromIntegral n))
nested = map (\p -> let m = (n `div` p)
                    in  map (\j -> j*p) [2..m]
            ) sqrt_primes
not_primes  = reduce (++) [] nested
```

Normalize the nested map:
```
sqrt_primes = primesOpt (sqrt (fromIntegral n))
nested = map (\p ->
                let m   = n `div` p      in    -- distribute map
                let mm1 = m - 1          in    -- distribute map
                let iot = iota mm1       in       -- F rule 4
                let twom= map (+2) iot   in       -- F rule 2
                let rp  = replicate mm1 p in      -- F rule 3
                in  map (\(j,p) -> j*p) (zip twom rp) -- F rule 2
            ) sqrt_primes
not_primes  = reduce (++) [] nested      -- ignore, already flat
```
Flattening PrimeOpt was part of PMPH's Weekly Assignment 2!
